- C. Summary

A. Global (volume averaged) chemistry models

Global (volume averaged) chemistry models

- The main idea of a global model is to generate a model that encompasses a large number of reactions in order to model a processing plasma with a limited computing power by neglecting the complexity which arises when spatial variations are considered
- Thus the model does not describe spatial distribution but captures scalings of plasma parameters with control parameters
- The model allows us to investigate various phenomena, such as the effects of excited species, negative ions and particular reactions on the overall discharge

A.1 Global (volume averaged) chemistry models – oxygen

The oxygen discharge

- The oxygen discharge is of significance in various materials processing applications including
 - etching of polymer films
 - ashing of photoresist
 - oxidation
- The oxygen chemistry is complicated due to the presence of metastable atomic and molecular species
- It is in particular the two low lying metastable molecular states designated by a¹Δ_g and b¹Σ⁺_g, which are located 0.98 and 1.627 eV above the ground state, respectively
- It is well established that collisions with these metastable states have in many cases larger cross sections and thus higher reaction rates than corresponding collisions with the ground state molecule

イロト イ理ト イヨト イヨト

Sac

- A steady state global (volume averaged) model was developed for the oxygen discharge
- The following species are included
 - electrons
 - the ground state oxygen molecule $O_2(X^3\Sigma_g^-, v = 0)$,
 - The metastable oxygen molecules O₂(a¹∆_g), O₂(b¹Σ⁺_g) and the metastable Herzberg states O₂(A³Σ⁺_u, A'³∆_u, c¹Σ⁻_u)
 - the ground state oxygen atom O(³P)
 - the metastable oxygen atom O(¹D)
 - the negative oxygen ions O⁻ and O⁻₂
 - the positive oxygen ions O⁺ and O₂⁺
 - \blacksquare Ozone O_3 and its ions O_3^+ and O_3^-
- The content of the chamber is assumed to be nearly spatially uniform and the power is deposited uniformly into the plasma bulk

200

The particle balance equation for a species X is given

$$\frac{\mathrm{d}n^{(X)}}{\mathrm{d}t} = \mathbf{0} = \sum_{i} R_{\mathrm{Generation},i}^{(X)} - \sum_{i} R_{\mathrm{Loss},i}^{(X)}$$

where $R_{\text{Generation},i}^{(X)}$ and $R_{\text{Loss},i}^{(X)}$, respectively, are the reaction rates of the various generation and loss processes of the species *X*

The power balance equation, which equates the absorbed power P_{abs} to power losses due to elastic and inelastic collisions and losses due to charged particle flow to the walls is given as

$$\frac{1}{V} \left[P_{abs} - eVn_{e} \sum_{\alpha} n^{(\alpha)} \mathcal{E}_{c}^{(\alpha)} \kappa_{iz}^{(\alpha)} - eu_{B0}n_{i}A_{eff}(\mathcal{E}_{i} + \mathcal{E}_{e}) \right] = 0$$

For the edge-to-center positive ion density ratio we use

$$\begin{split} h_{\ell} \simeq & \left[\left(\frac{0.86}{(3 + \eta L/2\lambda_{\rm i})^{1/2}} \frac{1}{1 + \alpha_0} \right)^2 + h_{\rm c}^2 \right]^{1/2} \\ h_{\rm R} \simeq & \left[\left(\frac{0.8}{(4 + \eta R/\lambda_{\rm i})^{1/2}} \frac{1}{1 + \alpha_0} \right)^2 + h_{\rm c}^2 \right]^{1/2} \end{split}$$

where $\alpha_0 \approx (3/2)\alpha$ is the central electronegativity, $\eta = 2T_+/(T_+ + T_-)$ and

$$h_{\rm c} \simeq \left[\gamma_{-}^{1/2} + \gamma_{+}^{1/2} \left[n_{*}^{1/2} n_{+} / n_{-}^{3/2}\right]\right]^{-1}$$
 and $n_{*} = \frac{15}{56} \frac{\eta^2}{k_{\rm rec} \lambda_{\rm i}} V_{\rm i}$

is based on a one-region flat topped electronegative profile

$$\gamma_- = T_e/T_-$$
 and $\gamma_+ = T_e/T_+$

Kim et al., J. Vac. Sci. Technol. A, 24 (2006) 2025 on Com

- The electron energy distribution function (EEDF) is usually assumed to be Maxwellian
- We can also assume a general electron energy distribution

$$g_{\rm e}(\mathcal{E}) = c_1 \mathcal{E}^{1/2} \exp\left(-c_2 \mathcal{E}^x\right)$$

$$c_{1} = \frac{1}{\langle \mathcal{E} \rangle^{3/2}} \frac{\left[\Gamma(\xi_{2})^{3/2} \right]}{\left[\Gamma(\xi_{1})^{5/2} \right]} \text{ and } c_{2} = \frac{1}{\langle \mathcal{E} \rangle^{x}} \frac{\left[\Gamma(\xi_{2}) \right]}{\left[\Gamma(\xi_{1}) \right]^{x}}$$

where $\xi_{1} = 3/2x$ and $\xi_{2} = 5/2x$ $g_{p}(\mathcal{E}) = \frac{g_{e}(\mathcal{E})}{\mathcal{E}^{1/2}}$

Here x = 1 and x = 2 correspond to Maxwellian and Druyvesteyn electron energy distributions, repectively

Gudmundsson PSST, 10 (2001) 76

• □ ▶ • □ ▶ • □ ▶

The diffusional losses of the neutral oxygen atoms (ground state and metastable) to the reactor walls are given by

$$k_{\rm O,wall} = \left[\frac{\Lambda_{\rm O}^2}{D_{\rm O}} + \frac{2V(2-\gamma_{\rm rec})}{Av_{\rm O}\gamma_{\rm rec}}\right]^{-1} \, \rm s^{-1}$$

- D_O is the diffusion coefficient for oxygen atoms
- $v_{\rm O} = (8eT_{\rm g}/\pi m_{\rm O})^{1/2}$ is the mean O velocity
- γ_{rec} is the wall recombination coefficient for neutral oxygen atoms on the wall surface
- Λ_O is the effective diffusion length of neutral oxygen atoms

$$\Lambda_{\rm O} = \left[\left(\frac{\pi}{L}\right)^2 + \left(\frac{2.405}{R}\right)^2 \right]^{-1/2}$$

 The wall recombination coefficient γ_{rec} is one of the most important parameter in oxygen discharge modelling

A.2.1 Model parameters

Surface recombination

- The wall recombination probability, γ_{rec}, is a very important quantity in all low pressure molecular discharges
- The pressure dependence on the wall recombination coefficient was achieved by fitting all the available data for stainless steel surfaces
- The same wall recombination coefficient was used for O(¹D) as no data is available

Gudmundsson and Thorsteinsson, PSST, 16 (2007) 399

Figure 1. The recombination coefficient of oxygen atoms at the chamber walls for stainless sets el as function of pressure. The measured data is taken from, o Singh *et al* [47], × Matsushita *et al* [90], \triangle Mozeüč and Zalat [91], \square Booth and Sadeghi [44] and * Gomez *et al* [40]. The solid line shows a fit to the measured data and the dotted line is a linear extrapolation from $\gamma = 0.5$ at 2mTor to $\gamma = 1.0$ at vacuum.

The wall recombination coefficient for oxygen atoms on stainless steel surfaces depends on pressure through

 $\gamma_{\rm rec} = 0.1438 \exp(2.5069/p)$ p > 2 mTorr

I D > I D > I D > I D > I

 $\gamma_{\rm rec} = -0.25p + 1 \quad p < 2 \, {\rm mTorr}$

A.2.3 Particle densities

Particle densities

- The dominant species is the oxygen molecule in the ground state O₂(X³Σ_g) followed by the oxygen atom in the ground state O(³P)
- The singlet metastable states O₂(a¹Δ_g) and O₂(b¹Σ⁺_g) and the metastable atom O(¹D) are also present in the plasma in significant amounts

a cylindrical stainless steel chamber

radius R = 15 cm and length L = 30 cm $P_{abs} = 500$ W

Toneli et al., J. Phys. D, 48 (2015) 325202

Particle densities

- The O₂(b¹Σ⁺_g) density overcomes the O₂(a¹Δ_g) density in the pressure range from 2.5 to 80 mTorr
- The O₂⁺ ions are in majority among the positive ions
- The O⁺ density has a sharp decrease for pressures above 4 mTorr
- The ratio [O⁻]/[O₂⁻] is 5.3 at 1 mTorr, and 1.3 at 100 mTorr
 - a cylindrical stainless steel chamber

radius R = 15 cm and length L = 30 cm $P_{abs} = 500$ W

Toneli et al., J. Phys. D, 48 (2015) 325202

Creation of metastable $O_2(a^1 \Delta_g)$ *molecules*

Electron impact excitation (17)

$$e + O_2(X^3\Sigma_g^-) \longrightarrow O_2(a^1\Delta_g) + e$$

has 100 % contribution at 1 mTorr and 68.2 % at 100 mTorr

 The role of quenching of the metastable atom O(¹D) to create the metastable oxygen molecule (71)

$$O(^{1}D)+O_{2}(X^{3}\Sigma_{g}^{-}) \longrightarrow O_{2}(a^{1}\Delta_{g})+O(^{3}P)$$

reaches a maximum value, 20.1 % contribution at 12.5 mTorr, and 10.5 % at 100 mTorr

Toneli et al., J. Phys. D, 48 (2015) 325202

Destruction of metastable $O_2(a^1 \Delta_g)$ molecules

Electron impact dissociation (31,24)

$$e + O_2(a^1 \Delta_g) \longrightarrow O(^1D) + O(^3P) + e$$
$$e + O_2(a^1 \Delta_g) \longrightarrow O(^3P) + O(^3P) + e$$

are the most important channels for destruction of the metastable $O_2(a^1 \Delta_g)$ molecules, 57.2 % contribution at 1 mTorr and 38.1 % at 100 mTorr

Creation of metastable $O_2(b^1 \Sigma_g)$ *molecules*

 The most important contributor to the formation of the metastable oxygen molecule O₂(b¹Σ_g) is reaction 72

$$O(^{1}D)+O_{2}(X^{3}\Sigma_{g}^{-}) \longrightarrow O_{2}(b^{1}\Sigma_{g})+O(^{3}P)$$

which has 75.7 % contribution at 1 mTorr and 93.2 % at 100 mTorr

 This reaction has been suggested in the past to be a major contributor to the formation of b¹Σ⁺_g state in the atmosphere

Toneli et al., J. Phys. D, 48 (2015) 325202

Destruction of metastable $O_2(b^1 \Sigma_g)$ molecules

- Wall quenching is an important loss process for O₂(b¹Σ_g)
- Electron impact dissociation (38,34)

$$e + O_2(b^1 \Sigma_g) \longrightarrow O(^1D) + O(^3P) + e$$

$$e + O_2(b^1 \Sigma_g) \longrightarrow O(^3P) + O(^3P) + e$$

are the most important channels for destruction along with electron impact ionization (33)

$$e + O_2(b^1 \Sigma_g) \longrightarrow O_2^+ + 2e$$

Toneli et al., J. Phys. D, 48 (2015) 325202

Destruction of the negative ion O^-

 At low pressure that the electron impact detachment (54),

 $e + O^{-} \longrightarrow O(^{3}P) + 2e$

is the main contributor

- Ion-ion mutual neutralization is also important
- As pressure increases, the contributions of these reactions become negligible

Destruction of the negative ion O^-

 As the pressure increases charge exchange (113)

$$O^- + O_2(X^3\Sigma_g^-) \longrightarrow O(^3P) + O_2^-$$

and detachment by collision with $O(^{3}P)$ (117)

$$O^- + O(^{3}P) \longrightarrow O_2(X^{3}\Sigma_{g}^-) + e$$

have increased contribution as well as detachment by collision with $O_2(b^1\Sigma_g)$ (reaction 116)

$$O^- + O_2(b^1 \Sigma_g) \longrightarrow O(^3 P) + O_2(X^3 \Sigma_g^-) + e^{-2g^2}$$

A.3 Summary

Summary

- A global model of O₂, discharge has been applied to explore the creation and destruction of the singlet metastable molecules O₂(a¹Δ_g), O₂(b¹Σ⁺_g)
- The singlet delta state O₂(a¹Δ_g) is created mainly by lectron impact excitation

$$e + O_2(X^3\Sigma_g^-) \longrightarrow O_2(a^1\Delta_g) + e$$

■ The singlet delta state O₂(b¹Σ⁺_g) is created mainly by

$$\mathrm{O}(^{1}\mathrm{D}) + \mathrm{O}_{2}(\mathrm{X}^{3}\Sigma_{g}^{-}) \longrightarrow \mathrm{O}_{2}(\mathrm{b}^{1}\Sigma_{g}) + \mathrm{O}(^{3}\mathrm{P})$$

At low pressure that the electron impact detachment

$$e + O^- \longrightarrow O(^{3}P) + 2e$$

is the main contributor to the loss of $O^-_{(a) \rightarrow (a) \rightarrow (a)}$

B. 1D particle-in-cell/Monte Carlo collision simulation

■ The 1D particle-in-cell/Monte Carlo collision simulation

- The oxygen discharge
 - Capacitively Coupled Oxygen Discharge at 13.56 MHz Voltage Source – pressure dependence
- Summary

The 1D particle-in-cell/Monte Carlo collision simulation

The oopd1 1d-3v PIC/MCC code

- In particle-in-cell simulation the plasma is represented as a collection of macroparticles
- Each macroparticle is a charged "cloud" representing many real charged particles
- Each macroparticle has the same charge-to-mass ratio (q/m) as the real charged particle
- Equations of motion are solved for each macroparticle
- The electric and magnetic fields are calculated self-consistently using charge densities and currents produced by the macroparticles

The oopd1 1d-3v PIC/MCC code

- We use the oopd1 (objective oriented plasma device for one dimension) code to simulate the discharge
- The oopd1 code was originally developed at the Plasma Theory and Simulation Group at UC Berkeley
- It has 1 dimension in space and 3 velocity components for particles (1d-3v)
- The oopd1 code is supposed to replace the widely used xpdx1 series (xpdp1, xpdc1 and xpds1)
- It is developed to simulate various types of plasmas, including processing discharges, accelerators and beams

- Modular structure
- Includes relativistic kinematics
- Particles can have different weights

Gudmundsson et al., Plasma Sources Sci. Technol., 22 035011 (2013)

B.1. The oxygen discharge

The oxygen discharge

We consider a discharge that consists of:

- electrons
- the ground state oxygen molecule O₂(X³Σ⁻_g)
- the metastable oxygen molecule $O_2(a^1 \Delta_g)$
- the metastable oxygen molecule $O_2(b^1\Sigma_g)$
- the ground state oxygen atom O(³P)
- the metastable oxygen atom O(¹D)
- the negative oxygen ion O⁻
- the positive oxygen ions O⁺ and O⁺₂
- We apply a global model¹ beforehand to calculate the partial pressure of the various neutrals

Thorsteinsson and Gudmundsson, Plasma Sources Sci. Technol., 19 055008 (2010)

The oxygen discharge

The reaction set for the oxygen is comprehensive and for this study includes 67 reactions

Gudmundsson et al., Plasma Sources Sci. Technol., 22 035011 (2013), and 24 035016 (2015)

Image: 1 million of the second sec

B. 1. 1. Capacitively Coupled Oxygen Discharge at 13.56 MHz – pressure dependence – including $O_2(a^1 \Delta_a)$

We apply a voltage source with a single frequency

$$V(t) = V_{\rm rf} \sin(2\pi f t)$$

- The electrodes are circular with a diameter of 14.36 cm
- The gap between the electrodes is 4.5 cm
- We set $V_{\rm rf}$ = 222 V and f = 13.56 MHz
- The neutrals (O₂ and O) are treated as background gas at T_g = 300 K with a Maxwellian distribution
- The dissociation fraction and the metastable fraction is found using a global model
- The pressure is varied from 10 500 mTorr

- For a parallel plate capacitively coupled oxygen discharge at 50 mTorr with with a gap separation of 4.5 cm by a 222 V voltage source at 13.56 MHz
 - O₂⁺-ion density profile
 - O⁺-ion density profile
 - O⁻-ion density profile
 - electron density profile

Gudmundsson and Ventéjou (2015) JAP 118 153302

Sac

- The sheath width decreases as the pressure is decreased in the pressure range from 50 mTorr to 10 mTorr
- The sheath widths are largest at 50 mTorr
- As the pressure is increased from 50 mTorr up to 500 mTorr the sheath width decreases
- This agrees with what has been observed experimentally in the pressure range 40 – 375 mTorr

- \blacksquare The electron heating profile $\boldsymbol{J}_e \cdot \boldsymbol{E}$
- In the pressure range 50 500 mTorr the electron heating occurs almost solely in the sheath region
- As the pressure is decreased the Ohmic heating contribution in the plasma bulk increases and sheath heating decreases

Gudmundsson and Ventéjou (2015) JAP 118 153302

- At 10 mTorr excluding the metastable states in the simulation has very small influence on the heating mechanism
- At 50 mTorr the metastable states have a significant influence on the heating mechanism
- The role of the metastables is even more significant at 200 mTorr

Gudmundsson and Ventéjou (2015) JAP **118** 153302 Gudmundsson and Lieberman (2015) PSST **24** 035016

- At low pressure the EEPF is convex, the population of low energy electrons is relatively low
- As the pressure is increased the number of low energy electrons increases and the number of higher energy electrons (> 10 eV) decreases
- Thus the EEPF develops a concave shape or becomes bi-Maxwellian as the pressure is increased

Gudmundsson and Ventéjou (2015) JAP 118 153302

- Our results agree with the measurements of Lee et al. (2010) which explored experimentally the evolution of the EEPF with pressure in a capacitively coupled oxygen discharge in the pressure range 3 – 100 mTorr
- They find that the EEPF became more distinctly bi-Maxwellian and the density of low energy electrons increases as the gas pressure is increased

Lee et al. (2010) PRE 81 046402

- The effective electron temperature drops as the pressure is increased
- When the metastable singlet oxygen molecule O₂(a¹∆_g) is added to the discharge model the effective electron temperature drops, in particular in the electronegative core due to detachment by the metastable O₂(a¹∆_g) molecule

$$O^- + O_2(a^1 \Delta_g) \rightarrow \text{products}$$

Gudmundsson and Ventéjou (2015) JAP 118 153302

- At low pressure the EEPF is convex and develops a concave shape or becomes bi-Maxwellian as the pressure is increased
- These results contradict what is commonly found for the capacitively coupled argon discharge where the EEPF evolves from being concave at low pressure to being convex at high pressure

Gudmundsson and Ventéjou (2015) JAP 118 153302

B. 1. 2. Capacitively Coupled Oxygen Discharge at 13.56 MHz – pressure dependence – including O₂($a^1\Delta_g$), O₂($b^1\Sigma_g$) and $\gamma_{see}(E)$

 It has been known for decades that the metastable oxygen molecule O₂(b¹Σ_g) plays an important role in the oxygen discharge

Thompson (1961) Proc. Royal Soc. A 262(1311) 519

- Recent global model study indicates there is a significant density of O₂(b¹Σ_g) in the oxygen discharge
- The O₂(b¹Σ_g) is mainly created through

 The density profiles of charged particles and fast neutrals comparing including O₂(a¹Δ_g) (left) and O₂(a¹Δ_g) and O₂(b¹Σ_g) (right) at 50 mTorr

< □ > < 同 >

500

- The number of cold electrons increases as O₂(b¹Σ_g) is added to the discharge model
- The electron heating in the bulk drops to zero
- The EEPF is roughly independent of the pratial pressure of O₂(a¹∆_g) and O₂(b¹Σ_g) while both are included
- Adding secondary electron emission (γ_{see} = 0.2) leads to a high energy tail in the EEPF

- We have compiled experimental data from the literature on secondary electron emission yields for the species O₂⁺, O⁺, O₂ and O bombarding various metals and substances
- A fit was made through the available experimental data

Comparison to experimental findings:

o
$$\gamma_{\text{see}} = 0.0$$
,
4.4 % O₂(a¹ Δ_g)

+
$$\gamma_{see} = 0.0$$
,
4.4 % O₂(a¹ Δ_g) and 4.4 % O₂(b¹ Σ_g)

x $\gamma_{see} = \gamma_{see}(E)$, 4.4 % O₂(a¹ Δ_g) and 4.4 % O₂(b¹ Σ_g)

Experimental findings by Keckar

(Ph.D. Thesis, Dublin City University, January 2015)

Summary

- We demonstrated particle-in-cell/Monte Carlo collision simulation of a capcacitively coupled disharge
- In an oxygen discharge at low pressure the EEPF is convex and develops a concave shape or becomes bi-Maxwellian as the pressure is increased
- These results contradict what is commonly found for the capacitively coupled argon discharge where the EEPF evolves from being concave at low pressure to being convex at high pressure

C. Overall Summary

Overall Summary

- A global (volume averaged) model can be used to understand the plasma chemistry
 - Which particles are important
 - Which reactions are important
 - How do the plasma parameters scale with the control parameters – power, pressure, discharge dimensions
- Particle-in-cell/Monte Carlo collision simulations can be used to explore the plasma kinetics
 - To find the electron energy distribution function
 - To find the ion energy distribution (IED) and the ion angular distribution (IAD)
