Introduction

- In high power impulse magnetron sputtering (HiPIMS), the discharge is created by applying a high-power, unipolar pulse of low duty-cycle to the cathode target (Helmersson et al., 2005, 2006).
- The high-power pulse has a peak cathode voltage in the range 500 - 2000 V which gives peak power densities in the range 1 - 3 kW/cm\(^2\).
- For the high power impulse magnetron sputtering (HiPIMS) discharge, peak power is \(\sim 10^3\) kW/cm\(^2\), average power is \(\sim 5\) kW/cm\(^2\), no significant target heating.
- Repetition frequency 50 - 600 Hz.
- Duty cycle 5 - 50%.
- Electron density of the order of \(10^19 - 10^20\) m\(^{-3}\) has been reported in the substrate vicinity (Gudmundsson et al., 2001; Bohlmark et al., 2005a).
- A high fractional ionization of the sputtered vapor has been demonstrated and values higher than 90% have been reported (Bohlmark et al., 2005).
- Here we explore the spatial and temporal variation of the plasma parameters and the electron energy distribution in the HiPIMS discharge.

Experimental apparatus

- An array of 7 Langmuir probes was constructed and mounted into the chamber on a movable rod, which allows for axial movement of the probe array.
- Each Langmuir probe was made of a stainless steel wire, 200 µm in diameter and 5 mm long.
- Argon (Ar) of purity 99.9997%, was used as discharge gas.
- The discharge was operated in the pressures range 3 - 20 mTorr.
- A standard planar magnetron source was operated with a 130 mm diameter copper (Cu) target inside a stainless steel chamber, 460 mm in diameter and 525 mm long.
- The average power was in the range 215 - 270 W, corresponding to pulse energy 4.3 J - 5.4 J for pulse length 80 to 90 µs, depending on the gas pressure, and repetition frequency of 50 Hz.

Results and Discussion

- The EEDF is broad for the lower discharge pressure of 3 mTorr and it becomes narrow as the pulse progresses at both 3 mTorr and 20 mTorr (Gudmundsson et al., 2009).
- This indicates that the plasma cools off as the pulse progresses.
- There is a significant density of metal ions in a HiPIMS discharge which is expected to cool the EEDF due to electron impact excitation and ionization of the metal atoms, which have much lower excitation thresholds and ionization potential than the argon sputtering gas.
- High electron density leads to a Maxwellian-like low energy part of the electron energy distribution function. The depletion in the high energy part is partially due to escape of high energy electrons to the chamber walls.

Summary

- A Langmuir probe was applied to explore the electron density and the electron energy distribution function (EEDF), the effective electron temperature and the plasma potential during the “pulse-on” period in a HiPIMS discharge.
